PART ONE: Analysis on autos dataframe

- Upon looking at the information of the entire data frame, there are 5 out of a tota; 20 columns that have null or NaN data: vehicle, gearbox, model, fuelType, and notRepairedDamage. But none of the columns have more than 20% of its data as null values.
 - vehicleType: 5,095 null/NaN data
 gearbox: 2,680 null/NaN data
 model: 2,758 null/NaN data
 fuelType: 4,482 null/NaN data
 notRepairedDamage: 9,829 null/NaN data
- There are also 5 columns that have data that are int datatype: yearOfRegistration,powerPS,monthofRegistration,nrOfPictures,postalCode
- Also noticed some data columns have data that's spelled incorrectly, contain a combination of numbers and characters, and datetimes.
- I expected that we will be filling null cells with appropriate data, correcting misspelled words, and removing characters from number+char combos, creating datetime objects and extracting either the dates or the times, and converting the values (which would then be numbers) to either the int or float datatypes among other tasks.
- Some cells that have strings are also written in German, so I suspect that we would have to translate all of our non-english cells to english

```
}, inplace=True)
autos.columns
```

PART TWO: Renaming columns. - We renamed the columns whose names were in the camelcase format to the snakecase format because snakecase is the format most preferred in Python.

```

PART THREE: Noting descriptive info. about table data - nr_of-pictures column has a mean of 0.0 (and everywhere else on the stats sheet) and a count of 50,000 which means that all the data in that column are 0s - power_ps which is another name for Horse Power(HP), has a min of 0.00, which means that there are cars registered that can't run at all. - postal_code column has a min value of 1067. Postal codes are meant to be 5 digits long which indicates that there are some postal codes that start with a zero which doesn't get shown. In theory, the data type in this column have to be changed to the string type instead of int or float types in order to show that zero in the beginning of each postal code.

```
[7]: autos['price'] = autos['price'].str.replace('$','').str.replace(',','').

→astype(float)

autos['odometer'] = autos['odometer'].str.replace('km','').str.replace(',','').

→astype(float)
```

```

PART FOUR: Identifying and removing outliers - Based on the descriptions given above, you can already see a few outliers. For instance: the cheapest car you can get which is the min price value is 0. - So essentially you would be getting those cars for free. Thus, you would want to remove free cars from your dataframe because the car very low to no value. - You can also see that the max is another outlier, as the most expensive car in the dataframe is listed at 100 million dollars. The most expensive car in the world today costs 13 million dollars. Therefore, you would want to remove any cars priced at more than 13 million. - Ideally, the most accurate listings can be found between 1,100 and 13 million dollars in my opinion.

      max
```

There are a few discrepencies in the registration_year column. The minimum year is listed at year 1000 which is well before the first car was invented, and max year listed at year 9999 which is well into the future. Thus, we'll only looked at cars registered between 1900 - 2016 which will remove any years less than year 1900, and years more than year 2016.

```
[20]: autos = autos[autos["registration_year"].between(1900.0,2016.0)] autos["registration_year"].value_counts(normalize=True).head(10).sort_values
```

```
[20]: <bound method Series.sort_values of 2000

```

We can see above that the majority of cars were sold between 1998 and 2016.

When we look at high price ranges for the column, we can see a significant jump from 350K dollars and up. Therefore it is safe to remove any data with prices 350K dollars or more. You can also that there are some cars less that 100 dollars. It should be safe to keep the prices of any car a dollar and up since Ebay is a site well-known for auctioning off its products.

```
[21]: autos = autos[autos['price'].between(1, 350000)]
      autos.shape

      Name: last_seen, dtype: float64
```

The last_seen date column shows a spike in the last 3 days of sales. This is most likely due to the bidding war strategy when bidders typically wait until the last few days or the last day to make their final bids. The days prior can't have any relevant effect since the percentages are pretty evenly distributed.

```

	Name: brand, dtyp	e: Iloat64

The top 5 car brands on this list are all German made. The top German brand more than doubles the next car brand from the next country. We'll limit our analysis to brands that accounts for more than 5% of the total sales data

```
[28]: brands = autos['brand'].value_counts(normalize = True)
most_common_brands = brands[brands > .05].index
most_common_brands
```

```
[29]: common_brand_dict={}
for brand in most_common_brands:
    selected_rows = autos[autos["brand"]==brand]
    mean_price = selected_rows["price"].mean()
    common_brand_dict[brand] = round(mean_price, 2)
import operator
brand_dict_sorted = sorted(common_brand_dict.items(), key=operator.
    itemgetter(1), reverse=True)
print('Average price for each car brand in the top 6 in descending order:', \_
    independent order: ', \_
    independe
```

```
Average price for each car brand in the top 6 in descending order: [('audi', 9336.69), ('mercedes_benz', 8628.45), ('bmw', 8332.82), ('volkswagen', 5402.41), ('ford', 3749.47), ('opel', 2975.24)]
```

As we can see, the cheapest commonly sold brands are ford and opel.

The most expensive commonly sold brands are audi and mercedes_benz.

The car brands commonly sold that are priced in between are bmw and volkswagen.

Out of the top 6 cars on the list, volkswagens are the most commonly sold car although it is priced in between which shows that customers not only value saving money, but they also value quality as well. Volkswagen cars are known for their top quality, safety, and engineering.

```

```
49999 20160406
```

```
[46681 rows x 20 columns]
```

Now let's take a look at whether or not there are price discrepencies based on whether or not cars with histories of damages have been repaired. We'll do this using a dictionary.

```
[45]: yes_no = ['yes','no']
damaged_prices = {}

for answer in yes_no:
    selected_rows = autos[autos['unrepaired_damage'] == answer]
    mean_price = selected_rows['price'].mean()
    damaged_prices[answer] = round(mean_price,2)
damaged_prices
```

```
[45]: {'yes': 2241.15, 'no': 7164.03}
```

We can see that cars with unrepaired damage are much cheaper than cars without damage on average.
